

Please replace the Abstract with the following amended Abstract:

~~A system for delivering sterile fluid to a patient, while preventing cross-contamination, in which flow interrupting means are provided which basically create regions where no fluid exists in the comprehensive or over-all quality of material that is flowing from a fluid source to a patient.~~ An injection apparatus for delivering fluid to multiple patients includes a first fluid source, a second fluid source, and a fluid path disposed between the first and second fluid sources and a patient. The fluid path includes a mixing device, a reusable portion for delivering fluid to multiple patients and a per-patient disposable portion removably connected to the reusable portion.
